Hospital Management Database

1. Introduction

The goal of the Hospital Management Database project is to design and implement a structured database system that efficiently manages hospital operations such as patient records, doctor information, appointments, and billing processes.

This system focuses on storing and organizing essential hospital data in a relational format using SQL. It helps in maintaining accurate records of patients, tracking doctor availability, managing visits, and handling billing details in an efficient and systematic manner.

MySQL Workbench is used to implement the project, where multiple related tables are created and linked using primary and foreign keys. This structured approach ensures data consistency and makes it easier to perform complex queries and generate meaningful reports.

2. Abstract

The Hospital Management Database project aims to develop a database system that can efficiently manage hospital-related data, including patients, doctors, visits, and billing information.

The system is designed using SQL and implemented in MySQL Workbench. It includes the creation of multiple tables such as Patients, Doctors, Visits, and Bills, each storing specific types of information. Relationships between these tables are established using primary and foreign keys to ensure data integrity.

Sample data is inserted into the tables to simulate real-world hospital operations. SQL queries are used to retrieve and analyze information such as appointment details, billing status, and patient records.

3. Tools Used

1.MySQL 8.0
2.MySQL Workbench 8.0
3.SQL (Structured Query Language)
4.dbdiagram.io

4. Steps Involved in Building the Project

1. **Database Creation**

A database named hospital_db was created to store all related data.

2. **Table Design**

Four main tables were created:

- Patients
- Doctors
- Visits
- Bills

Relationships were established using primary and foreign keys.

3. **Data Insertion**

Sample data was inserted into all tables to simulate real-world hospital scenarios.

This includes:

- Multiple patients with personal details
- Doctors with different specializations
- Visit records for appointments
- Billing details for each visit

4. **Stored Procedure Implementation**

A stored procedure was created to calculate the total bill amount automatically.

This procedure adds:

- Consultation fees
- Medicine charges
- Room charges

It ensures accurate and automated billing without manual calculation.

5. **Trigger Implementation**

A trigger was created to automate updates in the system.

When a patient's status is updated to **"Discharged"**, the trigger:

- Automatically updates the payment status in the Bills table to **"Paid"**

This helps maintain real-time data consistency and reduces manual work.

6. **Query Implementation**

Various SQL queries were written to analyze hospital data, including:

- Viewing all appointments
- Checking billing details
- Identifying pending payments

These queries help in retrieving meaningful insights from the database.

7. Report Generation

Reports were generated using SQL queries to summarize hospital operations:

- Patient Visit Report → Total visits per patient
- Doctor Performance Report → Number of patients handled
- Revenue Report → Total income generated

These reports help in decision-making and performance analysis.

8. Testing and Verification

All queries and functionalities were tested to ensure:

- Correct data insertion
- Proper working of relationships
- Accurate bill calculations
- Successful execution of triggers and procedures

5. Conclusion

The Hospital Management Database project successfully demonstrates how a structured database system can be used to manage hospital operations efficiently.

By using MySQL and SQL, the project shows how data related to patients, doctors, visits, and billing can be stored, managed, and analyzed effectively.

The use of relational tables and constraints ensures data integrity, while advanced features like stored procedures and triggers enhance automation and system reliability.
